1 Unsupervised learning: more results

All networks were trained for 100 epochs with a learning rate $\eta = 0.005$. Fig. 1 shows filters obtained by unsupervised training of a 784-32-32 network with linear activation ($C_k = \mathbb{R}^{d_k}$), ReLU-like activation ($C_k = \mathbb{R}_{>0}^{d_k}$) and hard-sigmoid activation function ($C_k = [0, 1]^{d_k}$). Fig. 2 illustrates the first layer filters for MNIST, KMNIST and FMNIST using the ReLU-type activation function.

The impact of the chosen activation function and dataset on the visual properties of the filters is evident. More constrained network activations leads to sparser filters, and the visual appearance of each dataset is also reflected in the filters.

2 Supervised Learning

2.1 Supervised learning from random initialization

A 784-64-64-10 ReLU-type LRRN network was trained for 100 epochs, using 20 BCD passes when inferring activations. A learning rate of 0.4 was used for MNIST and KMNIST and $\eta = 0.1$ was used for FMNIST. The reconstruction prefactors were chosen as $\beta = [1, 1, 0, 1]$ and the final layer was linear. The feedback parameter was chosen as $\gamma = 1/8$, and a batch size of 10 was used.
Figure 3: Loss and classification accuracies for a 784-64-64-10 ReLU-type LRRN. An accuracy of 97.2% is achieved for MNIST, 85.8% for KMNIST, and 86.4% for FMNIST.

2.2 Supervised learning with unsupervised pretraining
Three 784-64-64-10 LRRNs were trained on MNIST, KMNIST and FMNIST in an unsupervised manner by minimizing the free energy. A learning rate of $\eta = 0.005$ was used for all the networks. Furthermore $\beta = [1, 1, 0]$, $\gamma = 1/8$, and a mini-batchsize of 10. The resulting filters are shown in Fig. 6. The networks were then trained with supervision for additional 100 epochs. Fig. 7 depict the fine-tuned first layer filters, which retained most of their interpretable appearance. Fig. 5 shows the learning progress in terms of training loss and test accuracies. Pretraining leads to slightly better classification results, especially for the KMNIST dataset (85.8% vs. 87.91%).

Figure 5: Loss and classification accuracies for the supervised training phase of a 784-64-64-10 ReLU-type LRRN. An accuracy of 97.76% is achieved for MNIST, 87.91% for KMNIST, and 86.66% for FMNIST.

2.3 The impact of weight decay on the Lipschitz estimates
Tables 1 and 2 list the estimates for the Lipschitz constants $\rho$, the classification margin $m$ and the allowed $\ell_2$ norm $\delta$ for safe perturbations for two different weights on the weight decay term ($10^{-5}$ and $10^{-4}$). The upper bound on $\delta$ has been calculated via $\delta \leq \frac{m}{\sqrt{2}\rho}$. Higher weight decay regularization clearly induces a tradeoff between accuracy and perturbation robustness.
Figure 6: First layer filters of 784-64-64-10 ReLU-LRRNs after 20 epochs of unsupervised training.

Figure 7: First layer filters of the same 784-64-64-10 ReLU-LRRNs as shown in Fig. 6 after an additional 100 epochs of supervised training.
